# Playing with sets

## How “similar”?

User 1: {Murray Gell-Mann, Sheldon Cooper, Leonard Susskind, Rajesh Kuthrapalli}

User 2: {Sheldon Cooper, Murray Gell-Mann, Howard Wolowitz, Rajesh Kuthrapalli, Leonard Hofstadter}

Why bother? Find similar users, filter out “similar” results etc.

# Jaccard similarity coefficient

Given two *discrete* sets  $A$  and  $B$ :

- $J(A, B) = \frac{|A \cap B|}{|A \cup B|}$  (Jaccard coefficient)
- $c(A, B) = \frac{|A \cap B|}{|B|}$  (containment of  $A$  in  $B$ )

## Estimation

$J(A, B)$  (also known as *resemblance*) measures the extent to which  $A$  and  $B$  overlap

$c(A, B)$  measures extent to which  $A$  is a subset of  $B$

# Estimating similarity coefficients

## Expensive to do exactly...

- Linear if we use a hash table (needs the hash table)
- Can be overly expensive in many cases
  - E.g.: detecting almost duplicates in the Web

## How to proceed...

Use compact set representations

## Estimating similarity coefficients - Idea

- Assume we have a family  $\mathcal{H}$  of hash functions that permute  $[n] = \{0, \dots, n-1\}$
- Example ( $n = 10$ ): for a particular  $h \in \mathcal{H}$  and the set (2 5 8 9) we might have:

... hence applying  $h(\cdot)$  we obtain the set (4 8 9 10) in this case

## Estimating similarity coefficients - cont.

Assume we extract  $h$  uniformly at random from  $\mathcal{H}$ ...

What does it mean to extract u. a. r.?

Depends on how you define  $\mathcal{H}$

Example: if  $\mathcal{H} = \{(ax + b \bmod p) \bmod n\}$ , with  $a, b \in \{0, \dots, p-1\}$  for  $p$  prime,  $p > n$  this means choosing  $a, b$  u.a.r. in  $\{0, \dots, p-1\}$

- For every  $h$  and  $X \subseteq [n]$ , let  $h(X)$  denote the image of  $X$  under  $h$  and  $\min\{h(X)\} = \min_{x \in X} h(x)$
- $\mathcal{H}$  is *min-wise independent* if, once  $h$  is chosen u.a.r. from  $\mathcal{H}$  we have:

$$\mathbf{P}[\min\{h(X)\} = h(z)] = \frac{1}{|X|}, \forall z \in X$$

## Estimating similarity coefficients - cont.

Assume  $\mathcal{H}$  is min-wise independent

Consider two sets  $A, B \subseteq [n]$

Theorem ([Broder et al., 2000])

Assume  $h$  is chosen u.a.r. from  $\mathcal{H}$ . Then:

$$\mathbf{P}[\min\{h(A)\} = \min\{h(B)\}] = J(A, B) = \frac{|A \cap B|}{|A \cup B|}$$

In the picture:  $|A \cap B| = 6$ ,  $|A \cup B| = 16$ ,  $J(A, B) = 0.375$

## Estimating similarity coefficients - cont.

### Proof idea

- $\min\{h(A)\} = \min\{h(B)\}$  if and only if  $\min\{h(A \cup B)\} = h(z)$ , with  $z \in A \cap B$
- All items in  $A \cup B$  have equal chances of being the minimum
- $\mathbf{P}[\arg \min\{h(A \cup B)\} \in A \cap B] = \frac{|A \cap B|}{|A \cup B|}$

If one of these points becomes minimum then  $\min\{h(A)\} = \min\{h(B)\}$

# How to proceed in practice?

Given:

A collection of sets. E.g.: each set is a handy's address book containing a set of names, such as: ("S. Cooper", "L. Hofstadter", "R. Kuthrapalli", "H. Wolowitz")

Step 0: Pick  $m$  hash functions  $h_1, \dots, h_m$  u.a.r. from a min-wise independent family  $\mathcal{H}$ , with  $h_i : [n] \rightarrow [n]$

For each set  $X$ :

- 1 (If necessary) map  $X$ 's items to integers in  $[n]$  (use same encoding for all sets)
- 2 Compute  $M_i(X) = \min\{h_i(X)\}$ ,  $i = 1, \dots, m$

$(M_1(X), \dots, M_m(X))$  is  $X$ 's *fingerprint*. To estimate  $J(A, B)$ :

$$J(A, B) \simeq \frac{\sum_{i=1}^m (M_i(A) == M_i(B))}{m}$$

**Q.:** can you figure out why?

# Applying to user-user recommendations/1

## Users and their profiles:

Each user is represented by an incidence vector

$\vec{u} \in \{0, 1\}^n : \vec{u}_x = 1$  if  $u$  purchased (browsed, considered ...) item  $x$ , 0 otherwise

## Representing a user's profile in compact form

User  $u$ , i.e.,  $\vec{u}$ , is represented by a fingerprint

$F(u) = (M_1^u(X_u), \dots, M_m^u(X_u))$ , where  $X_u$  is the set of items purchased (browsed, considered ...) by  $u$

## Computing fingerprints

For  $i = 1, \dots, m$ ,  $M_i^u(X_u)$  is computed by hashing the set  $X_u$  using the  $i$ -th hash function, as shown before

# Applying to user-user recommendations/2

## User similarity

The similarity between two users  $u$  and  $v$  is given by their Jaccard coefficient:

$$J(u, v) = \frac{\vec{u} \cdot \vec{v}}{\sum_{x=1}^n (\vec{u}_x \text{ OR } \vec{v}_x)}$$

## Estimating user similarity

$$J(u, v) \simeq \frac{\sum_{i=1}^m (M_i^u(X_u) == M_i^u(X_v))}{m}$$

## Neighbourhood

Neighbourhood can be of fixed size or threshold based, as before

## Applying to user-user recommendations/3

### Estimating z-scores

$$\hat{z}_{Joe}(x) = \sum_{v \in Pool} \frac{J(Joe, v)}{J_{Joe}} z_v(x),$$

where  $J_{Joe} = \sum_{v \in Pool} J(Joe, v)$  and the  $z_v(x)$  as usual is computed from  $v$ 's past ratings

### Making a prediction

$$\hat{r}_{Joe}(x) = \mu_{Joe} + \sigma_{Joe} \hat{z}_{Joe}(x)$$

as before

### Note

Ratings are not used to compute user pairwise similarities but they are used to compute z-scores

## What else?

Perfect, min-wise independent hash functions can be very expensive

- $\Omega(n \log n)$  truly random bits necessary [Broder et al., 2000]
- In practice: use pairwise independent hash functions [Carter and Wegman, 1979] or approximate min-wise independent families of small (roughly logarithmic) size [Indyk, 1999]

Pairwise independent hash functions

- $\mathcal{H} = \{(ax + b \bmod p) \bmod n\}$ , for  $p$  prime,  $p > n$
- with  $a$  chosen u.a.r.  $\{1, \dots, p - 1\}$ ,  $b$  chosen u.a.r.  $\{0, \dots, p - 1\}$
- In practice,  $p$  might be the Mersenne prime  $2^{31} - 1$  in many cases
