SDCI 2012 Winter School: Hot Topics in Secure and  
Dependable Computing for Critical Infrastructures

January 15<sup>th</sup>-19<sup>th</sup>, Cortina D'Ampezzo, Italy

# Model-based dependability analysis

---

- ▶ A model of the system is constructed
  - ▶ Abstraction of the system that highlights features that are relevant for the analysis and neglects the other details
- ▶ Advantages of model-based analysis
  - ▶ It does not require to exercise a real instance of the system
  - ▶ Allows “what-if analysis” and sensitivity analysis
  - ▶ Allows to assess the system in extreme conditions
- ▶ Common models that are used in dependability analysis
  - ▶ Combinatorial models
    - ▶ Fault-Trees (FT), Reliability Block Diagrams (RBD)...
  - ▶ State-based models
    - ▶ Continuous Time Markov Chains (CTMC)
    - ▶ Stochastic Petri Nets (SPN)
    - ▶ ...

# Challenges in LCCI modeling

---

## ▶ Challenges

- ▶ Very high number of components
- ▶ Components are interconnected, leading to complex dependencies and interdependencies
- ▶ Dependencies evolve during time (also because of external events)
  - ▶ The failure of a router in a communication network
  - ▶ A tree touching a power transmission line...
- ▶ Challenges are getting also harder by the increasing adoptions of
  - ▶ Decentralized architectures
  - ▶ Wireless connectivity
  - ▶ Mobile application scenarios
  - ▶ COTS components
- ▶ Moreover: infrastructures are also interdependent on each other
  - ▶ The power distribution infrastructure relies on network communication for monitoring and control
  - ▶ Network communication needs electric power

# Two complementary approaches

---

- ▶ The following properties of models are very welcome in facing these challenges:
  - ▶ Scalability – To address the high number of components and connections
  - ▶ Reusability – LCCIs are often characterized by groups of components having similar behavior
  - ▶ Modularity – Facilitates handling the interdependencies
  - ▶ Maintainability – Changes are easier to address: LCCIs evolve over time and their lifetime is typically several years
- ▶ In the following, two complementary approaches to achieve these properties are presented
  - ▶ System decomposition and modular model construction
  - ▶ Automated model construction by transformations

# System decomposition / 1

---

- ▶ Main “building blocks” of the system are identified
- ▶ Usually, the system is decomposed considering
  - ▶ Different components (System-level decomposition)
  - ▶ Different layers and functionalities within components (Component-level decomposition)
    - ▶ User layer: Models the interaction of the user (if any) with the component
    - ▶ Application layer: Models the main functionalities of the component
    - ▶ Architecture layer: Models the dependability behavior of the component
- ▶ **Interfaces between submodels should be carefully identified**
  - ▶ Submodels should communicate only through those interfaces
  - ▶ The behavior of submodels should be independent of each other

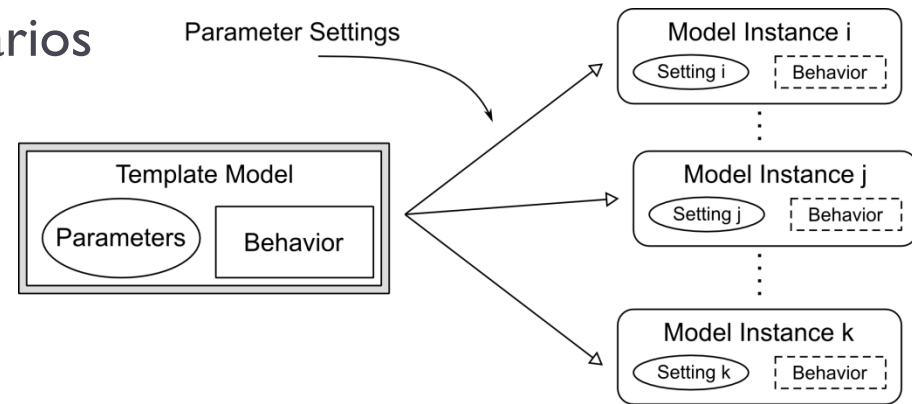

# Template models

## ▶ Parameters

- ▶ Often system components have similar functionalities, but different operating conditions and setup parameters
- ▶ The behavior of submodels should not depend on those parameters
- ▶ **“Template” submodels are built, based on a set of parameters**
- ▶ These templates are then instantiated multiple times with different parameters
- ▶ And composed to obtain the overall model

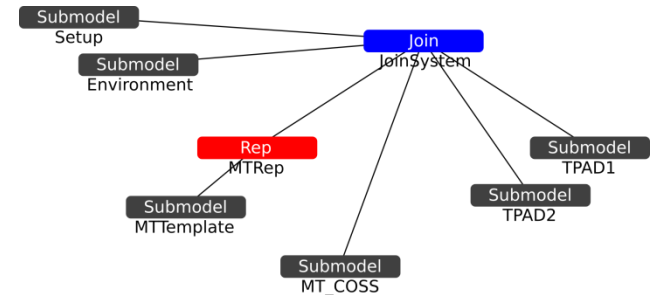

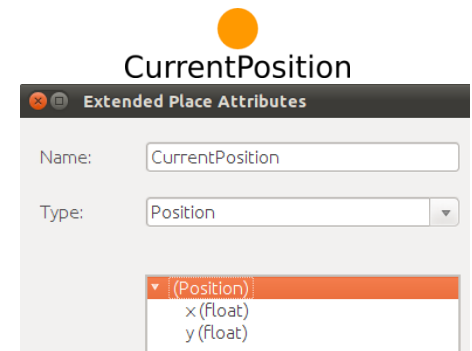

## ▶ **Advantages:**

- ▶ Easier to evaluate different scenarios
- ▶ Possible mistakes in model construction are reduced
- ▶ Easier to modify and maintain the model (changes to template are propagated)

# SAN implementation

- ▶ **Stochastic Activity Networks (SAN)**
  - ▶ Graphical formalism that extends Stochastic Petri Nets
  - ▶ Some useful features that can be exploited for this approach
- ▶ **Extended places**
  - ▶ Not limited to hold an integer number of tokens
  - ▶ Can hold C++ basic types, structures, arrays, or a combination of those (e.g., an array of structures)
  - ▶ Very useful to hold submodel parameters
- ▶ **Join/Replicate composition formalism**
  - ▶ Allows to compose different instances of submodels at multiple levels
- ▶ A special submodel “Setup” sets the actual parameters of instances

# Application to LCCIs

- ▶ This kind of approach is tailored to LCCIs, and has already been used to model kind of systems
- ▶ HIDENETS “Car-accident” use-case

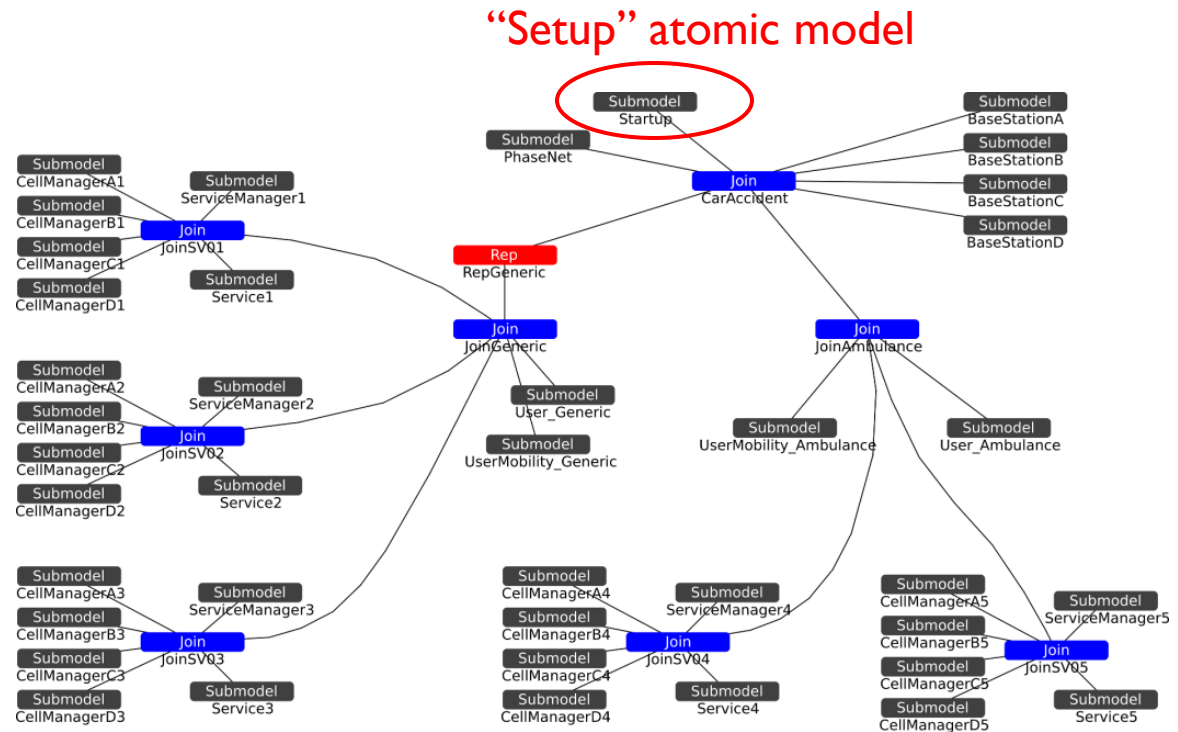

- ▶ 40 model instances
- ▶ Based on 10 templates

## Services:

- ▶ Different load factors
- ▶ Possibly also different based on the cell

## Base stations:

- ▶ Different locations
- ▶ One is subject to outages while the other are not

# CBD and MDE methodologies

---

- ▶ The second approaches takes advantage of two popular software development methodologies:
- ▶ **Component-Based Development (CBD)**
  - ▶ The system is obtained by composition of a predefined set of components, having well-defined interfaces
- ▶ **Model-Driven Engineering (MDE)**
  - ▶ Models are considered the main entities in the development process
  - ▶ The system is described using an high-level engineering language (UML, AADL, SysML...)
  - ▶ Then, artifact are generated by automatic transformations
    - ▶ Code
    - ▶ Representation in other modeling languages
    - ▶ Analysis models

# Dependability analysis in MDE and CBD

---

- ▶ **Workflow:**
  - ▶ The functional model of the system is built by composition of several components and interfaces, using UML-like languages
  - ▶ The model is then enriched with dependability attributes
  - ▶ Automated transformations generate the analysis model
  - ▶ The model is solved using the analysis tool, and results are back-annotated in the original model
- ▶ **Incremental process:** the resulting model can be used as input to subsequent analyses
- ▶ Which dependability properties should be represented in the high-level modeling language?
  - ▶ No agreed answer or standardized solution yet
  - ▶ Standards exist in other domains: real-time and schedulability (“MARTE” profile), quality of service (“QoS&FT” profile)

# CHES

- ▶ CHES (Composition with guarantees for High-integrity Embedded Software components assembly) 
- ▶ Objective: Define and develop a methodology based on CBD and MDE that allows to specify and evaluate non-functional properties
- ▶ Real-time and embedded system domain
- ▶ CHES Modeling Language (CHES ML)
  - ▶ Language based on selected portions of UML, MARTE, and SysML
- ▶ CHES Dependability Profile
  - ▶ Allows to specify dependability properties on CHES ML models
  - ▶ Supports different dependability analysis techniques:
    - ▶ Fault-Tree Analysis (FTA)
    - ▶ Failure Modes, Effects [and Criticality] Analysis (FMEA and FMECA)
    - ▶ State-based analysis (using Stochastic Petri Nets)
    - ▶ Failure Transformation and Propagation Calculus (FTPC)

# CHESSE Dependability Profile: Key elements / 1

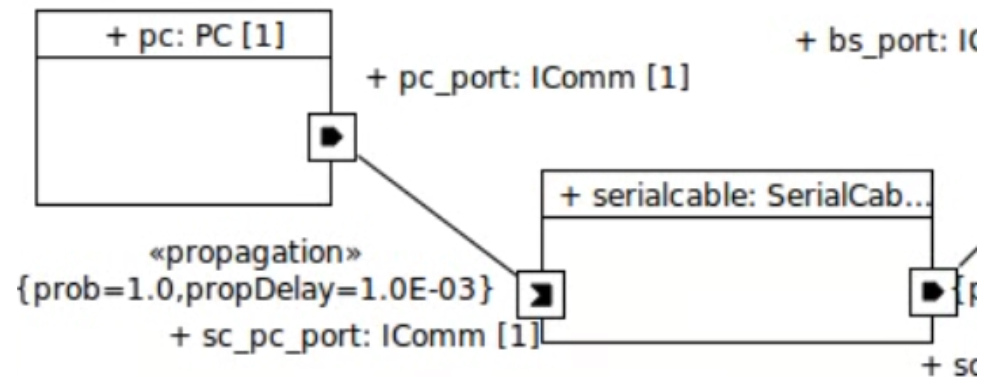

## ▶ Template stereotypes

- ▶ Define generic components,
- ▶ Represents a rapid way for users to provide dependability information on components

## ▶ Non-functional properties on connections and allocations

- ▶ Specify how propagation takes place between connected components
- ▶ Also propagation from hardware to software components

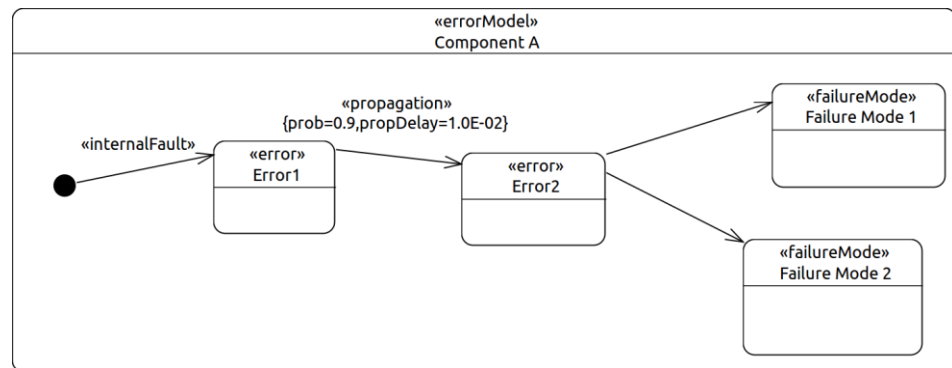

## ▶ Maintenance

- ▶ Means to model more complex maintenance policies

# CHESD Dependability Profile: Key elements /2

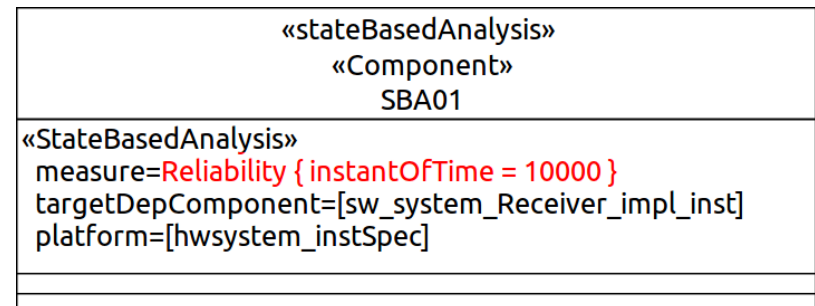

## ▶ CHESD Error Model

- ▶ Defined as a particular kind of StateMachine diagram
- ▶ Allows to define more complex behavior of components with respect to dependability
  - ▶ Internal faults
  - ▶ External faults
  - ▶ Errors
  - ▶ Failure modes

## ▶ Measures of interest

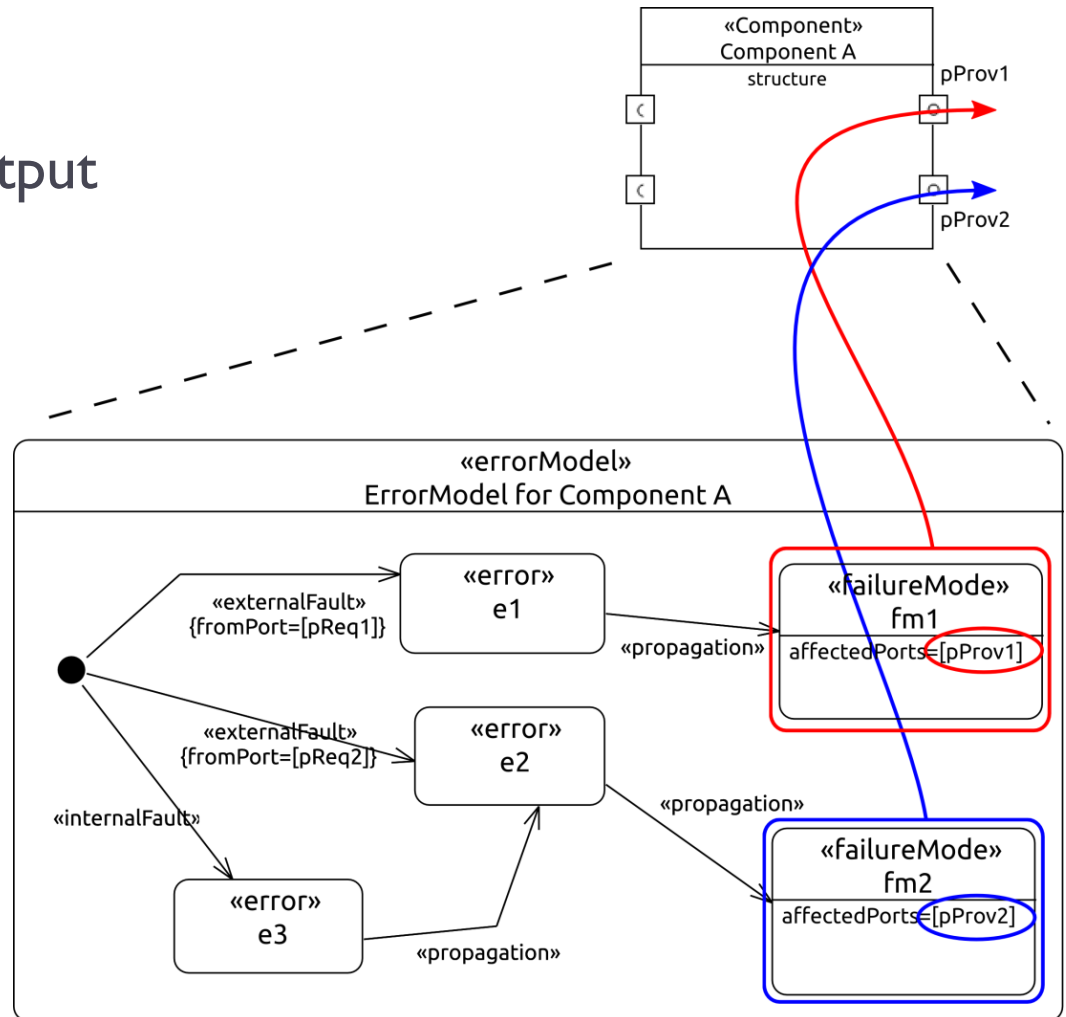

- ▶ Supports the definition of different measures of interest
- ▶ Currently implemented in transformations:
  - ▶ Instant of time reliability
  - ▶ Instant of time availability
  - ▶ Interval of time availability
- ▶ W.r.t. to either a single failure mode or a whole component

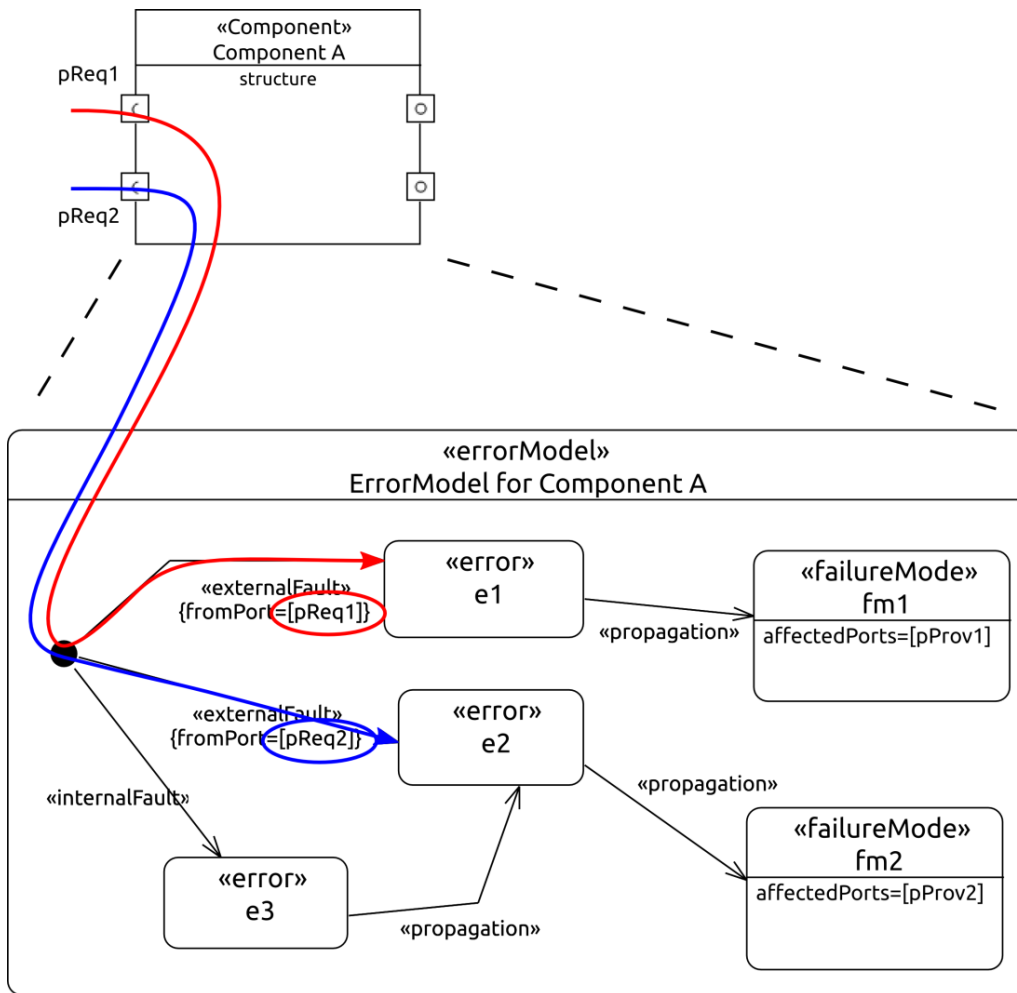

# Linking the error model and component interfaces / 1

- ▶ Failure modes
  - ▶ Associated with output (provided) ports of components

- ▶ Maps failure modes to services provided by the component

# Linking the error model and component interfaces /2

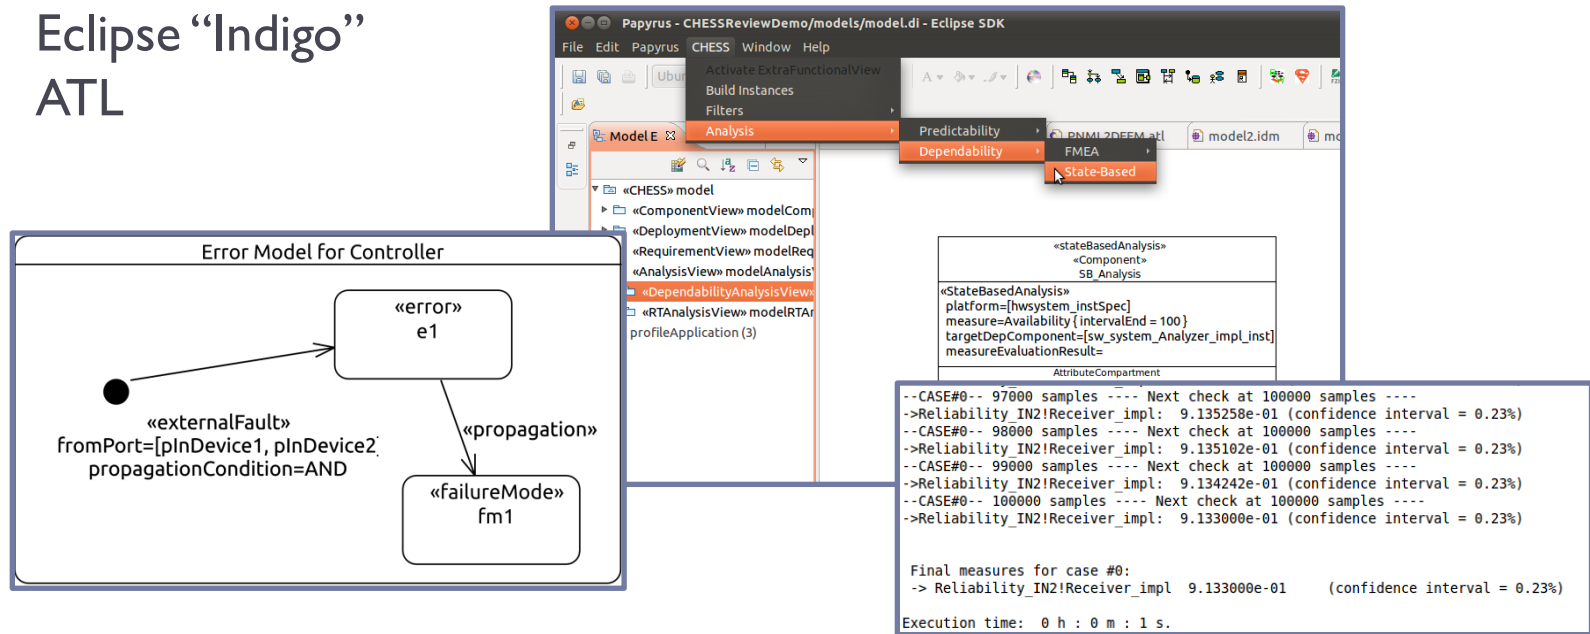

## ▶ External faults

- ▶ Associated with input (required) ports of components

- ▶ Maps external faults to services required by the component

# CHESS State-based analysis plugin

- ▶ Based on some of the latest technologies:
  - ▶ MDT/Papyrus
  - ▶ Eclipse “Indigo”
  - ▶ ATL

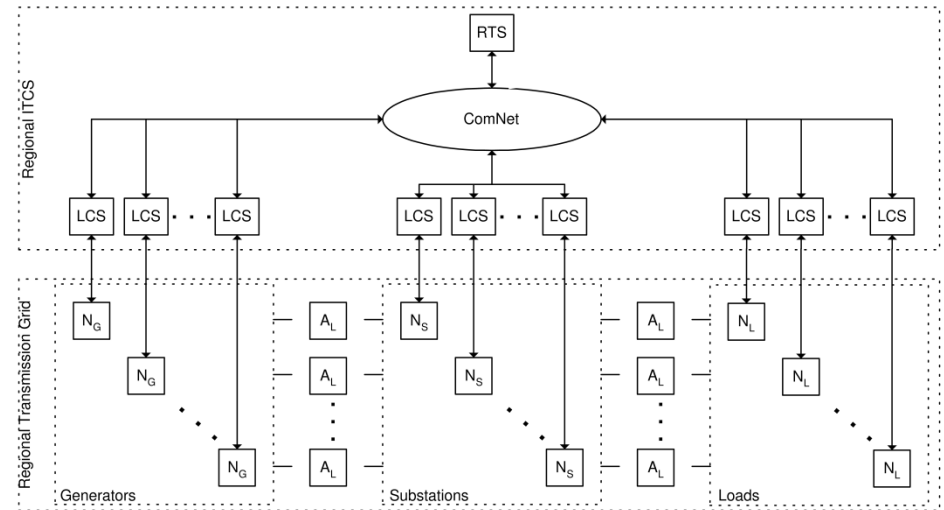

- ▶ Demonstration video is available online
  - ▶ <http://chess-project.ning.com/page/videos-1>
  - ▶ Set 2, Clip 2

# Application to LCCIs

- ▶ System composed of many similar components and many interconnections
  - ▶ Example: Electric Power Infrastructure
- ▶ Model the components and interconnections using a CBD approach
- ▶ Add non-functional properties
- ▶ Automatically derive propagation paths
  - ▶ Facilitates in spotting “cascading” and “escalating” failures
- ▶ UML profile for Critical Infrastructures modeling?

# Concluding remarks

---

- ▶ Presented two approaches to cope with system complexity in model construction
  - ▶ System decomposition and template models
  - ▶ Automated model generation by transformations
  
- ▶ Future work
  - ▶ Understand how these two approaches can be profitably combined
  - ▶ Extend the presented approaches to other contexts
    - ▶ LCCI (mainly for MDE-based approach)
    - ▶ Take into account aspects related to security
    - ▶ ...

Thank you!
